

# Genetics of Climate Adaptation Using Genome-Wide Association in Switchgrass

Tom Juenger<sup>1</sup>, Alice MacQueen<sup>1\*</sup>, The Switchgrass Genomics Team<sup>\*\*</sup>, Jason Bonette<sup>1</sup>, John Lovell<sup>2</sup>, Sujan Mamidi<sup>2</sup>, and Jeremy Schmutz<sup>2</sup>

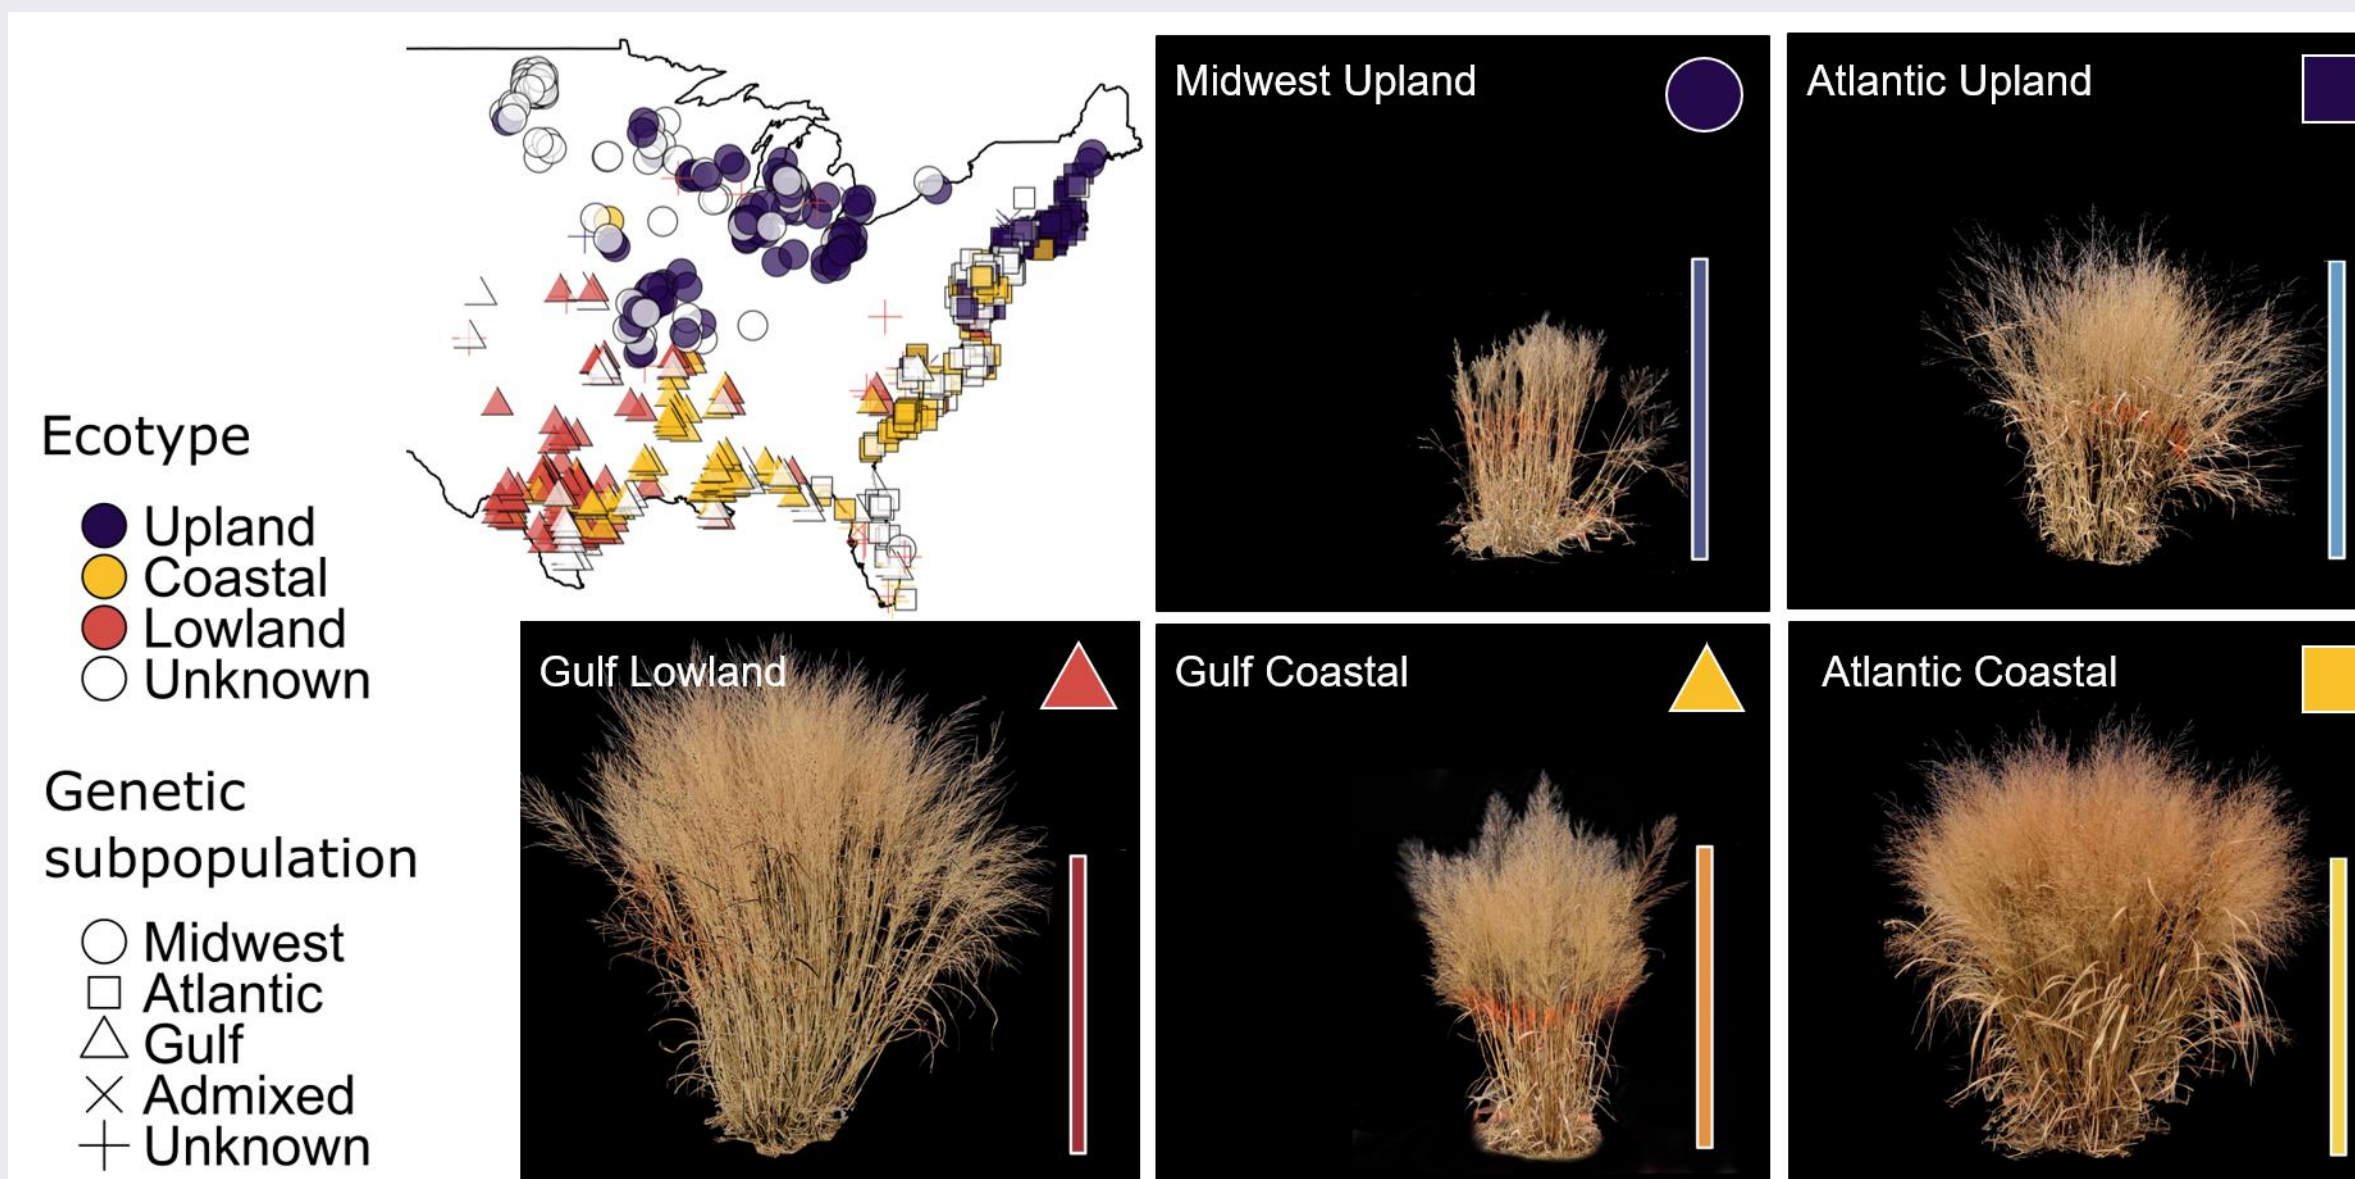

## Why Switchgrass?

**BIOFUELS:** Switchgrass (*Panicum virgatum*) is the model herbaceous bioenergy crop; it has high biomass yields and is productive on marginal lands; its ethanol yield can exceed that of maize on a per acre basis.

**CLIMATE ADAPTATION:** Natural switchgrass populations are found across North America east of the Rocky Mountains, and span eight USDA cold hardiness zones. Natural selection to climate has shaped the genetics of these populations and shaped phenotypic groupings into **upland** (mostly northern), **lowland** (mostly southern), and **coastal** ecotypes. These ecotypes likely have different adaptations to climate.

## Diversity Panel

Major phenotypic and genetic groups in the tetraploid switchgrass diversity panel. Plant specimens for the five major types are shown.

## Continent-Scale Adaptation Using Common Gardens

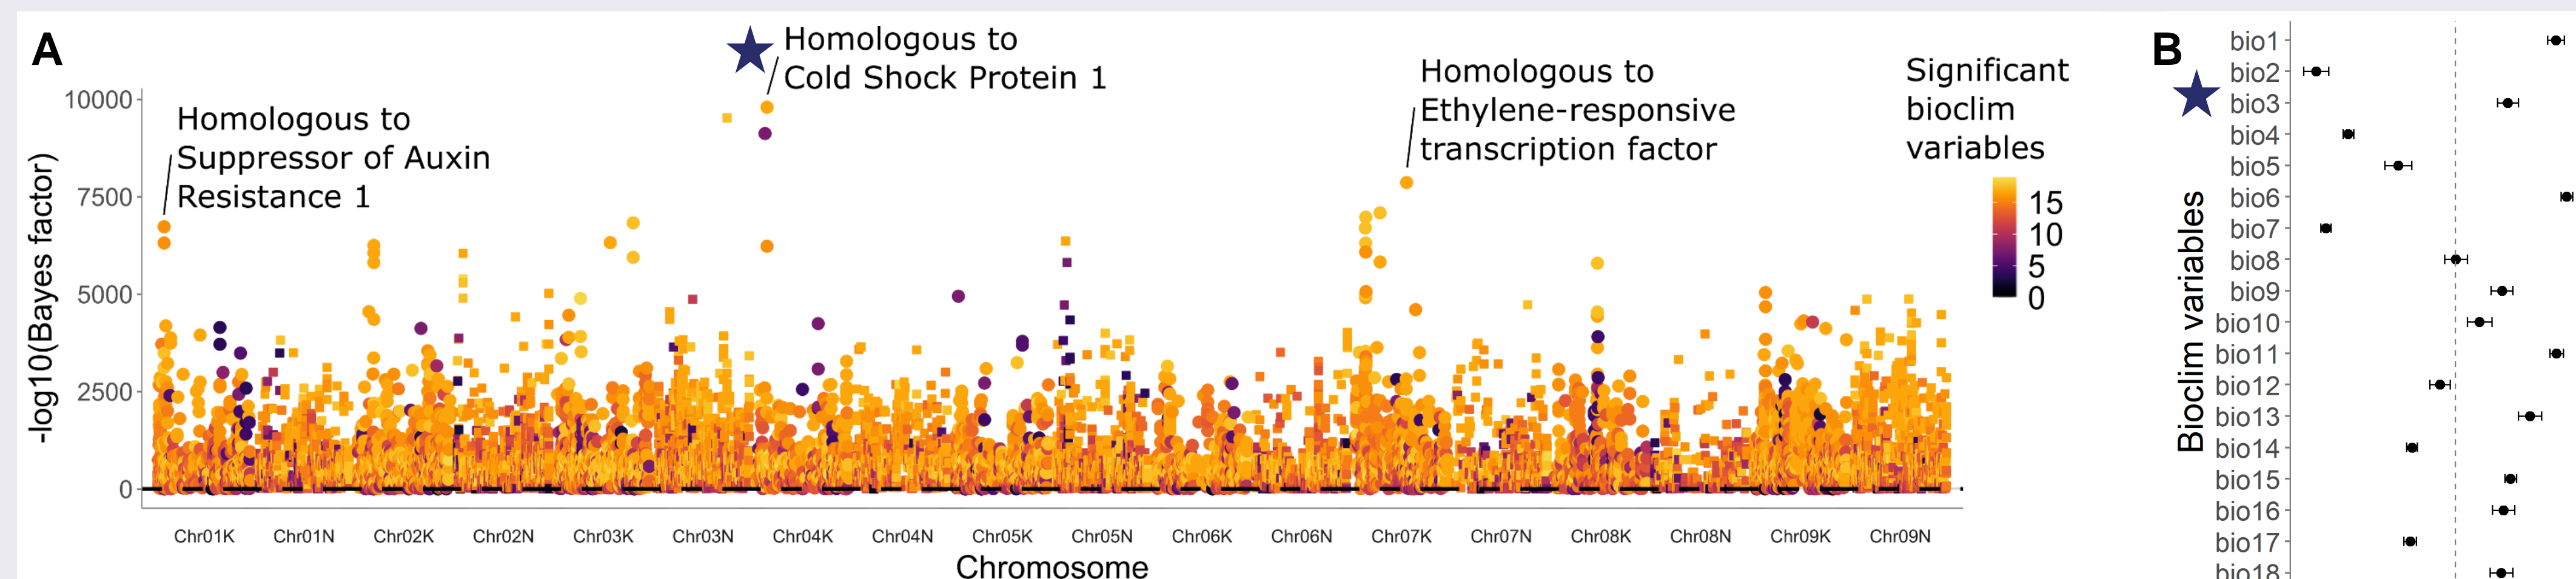

**A** The diversity panel was planted at ten common garden locations in 2018.

**B** Four northern common garden locations had significant overwinter plant death in winter 2018-2019.

**C** Specific gulf alleles were lost at high frequency in the north in the winter of 2018/2019. The fraction of alleles lost varied across the genome (first four chromosomes are shown).

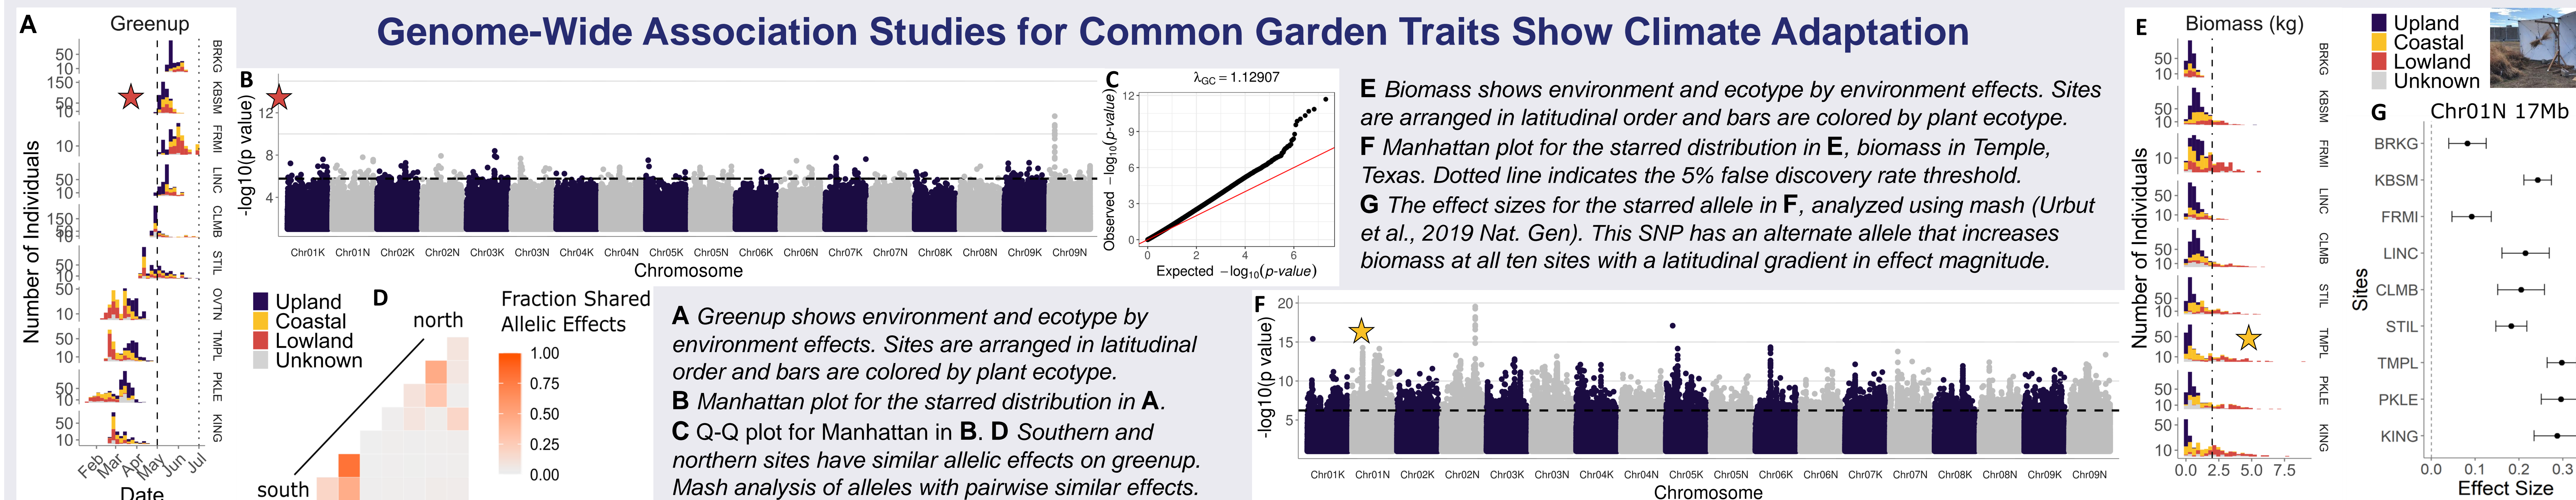

## Genome-Wide Association Studies of Environments at Plant Locations of Origin

SNPs with significant associations with one or more bioclim variable. **A** Significant SNPs were typically associated with 14-18 bioclim variables when analyzed with mash (Urbat et al., 2019 Nat. Gen.). Three nearby genes are noted.

**B** The starred allele in **A** has alternate alleles found in plants from consistent temperature, warmer climates.

## Genome-Wide Association Studies for Common Garden Traits Show Climate Adaptation

**A** Greenup shows environment and ecotype by environment effects. Sites are arranged in latitudinal order and bars are colored by plant ecotype.  
**B** Manhattan plot for the starred distribution in **A**.  
**C** Q-Q plot for Manhattan in **B**. **D** Southern and northern sites have similar allelic effects on greenup. Mash analysis of alleles with pairwise similar effects.

**E** Biomass shows environment and ecotype by environment effects. Sites are arranged in latitudinal order and bars are colored by plant ecotype.  
**F** Manhattan plot for the starred distribution in **E**, biomass in Temple, Texas. Dotted line indicates the 5% false discovery rate threshold.  
**G** The effect sizes for the starred allele in **F**, analyzed using mash (Urbat et al., 2019 Nat. Gen.). This SNP has an alternate allele that increases biomass at all ten sites with a latitudinal gradient in effect magnitude.

## Take-home message

Winter survival in the northern U.S. is a major selective agent in switchgrass.

Environmental GWAS show allelic effects that partition plants into "winter kill" and "non-winter kill" locations; e.g., warmer climates with more consistent temperatures (and more variable precipitation) versus cooler climates with more variable temperatures and more consistent precipitation.

Common garden phenotypes show genotype by environment interactions and strong signals of genetic association that vary by location.

## switchgrassGWAS R Package

<https://github.com/Alice-MacQueen/switchgrassGWAS>

1. Run Genome-Wide Association with ``pvdiv_gwas``
2. Find annotations with ``pvdiv_table_topsnps``
3. Analyze data at multiple sites using mash, with:  
``pvdiv_bigsnp2mashr``  
``mash_standard_run``  
``mash_plot_manhattan_by_condition``  
``mash_plot_effects``
